#### Abstract

An antimagic labeling of a finite undirected simple graph with $m$ edges and $n$ vertices is a bijection from the set of edges to the integers $1, \ldots, m$ such that all $n$-vertex sums are pairwise distinct, where a vertex sum is the sum of labels of all edges incident with the same vertex. A graph is called antimagic if it has an antimagic labeling. In 1990, Hartsfield and Ringel [N. Hartsfield, G. Ringel, Pearls in Graph Theory, Academic Press, INC., Boston, 1990, pp. 108-109, Revised version, 1994] conjectured that every simple connected graph, except $K_{2}$, is antimagic. In this article, we prove that a new class of Cartesian product graphs are antimagic. In particular, by combining this result and the antimagicness result on toroidal grids (Cartesian products of two cycles) in [Tao-Ming Wang, Toroidal grids are anti-magic, in: Proc. 11th Annual International Computing and Combinatorics Conference COCOON'2005, in: LNCS, vol. 3595, Springer, 2005, pp. 671-679], all Cartesian products of two or more regular graphs of positive degree can be proved to be antimagic.

Keywords: Antimagic; Magic; Labeling; Regular graph; Cartesian product

## 1. Introduction

All graphs in this paper are finite, undirected and simple. We follow the notation and terminology of [5]. In 1990, Hartsfield and Ringel [5] introduced the concept of antimagic graph. An antimagic labeling of a graph with $m$ edges and $n$ vertices is a bijection from the set of edges to the integers $1, \ldots, m$ such that all $n$-vertex sums are pairwise distinct, where a vertex sum is the sum of labels of all edges incident with that vertex. A graph is called antimagic if it has an antimagic labeling. Hartsfield and Ringel showed that paths $P_{n}(n \geq 3)$, cycles, wheels, and complete graphs $K_{n}(n \geq 3)$ are antimagic. They conjectured that all trees except $K_{2}$ are antimagic. Moreover, all connected graphs except $K_{2}$ are antimagic. These two conjectures are unsettled. In [2], Alon et al. showed that the latter conjecture is true for all graphs with $n$ vertices and minimum degree $\Omega(\log n)$. They also proved that complete partite graphs (other than $K_{2}$ ) and $n$-vertex graphs with maximum degree at least $n-2$ are antimagic. In [6], Hefetz proved several special cases and variants of the latter conjecture. In particular, he proved that for integers $k>0$ a graph with $3^{k}$ vertices is antimagic if it admits a $K_{3}$-factor. The main tool used in his paper is the Combinatorial NullStellenSatz (see [1]). In [7], Wang showed that the toroidal grids, i.e., Cartesian products of two or more cycles, are antimagic. In [3], the author proved that Cartesian products of two paths, or of a cycle and a path, are antimagic.

[^0]In this paper, we prove that the Cartesian products $G_{1} \times G_{2}$ of a regular graph $G_{1}$ and a graph $G_{2}$ of bounded degrees are antimagic, provided that the degrees of $G_{1}$ and $G_{2}$ satisfy some inequality. By combining this result and the antimagicness result on the Cartesian products of two cycles [7], all Cartesian products of two or more regular graphs of positive degree (not necessarily connected) can be proved to be antimagic. First, we introduce another concept about graph labeling called $\delta$-approximately magic.

Definition 1.1. A $\delta$-approximately magic labeling of a graph with $m$ edges is a bijection from the set of edges to the integers $1, \ldots, m$ such that the difference between the largest and the smallest vertex sums is at most $\delta$, where a vertex sum is the sum of labels of all edges incident with that vertex. A graph is called $\delta$-approximately magic if it has a $\delta$-approximately magic labeling.

Thus 0 -approximately magic is the same as magic in [5], or supermagic in some literature. We first prove some approximate magicness results on connected regular graphs, the following is proved in Section 2.

Theorem 1.1. If $G$ is an $n$-vertex $k$-regular connected graph $(k \geq 1)$, then $G$ is $\left(\frac{n k}{2}-1\right)$-approximately magic in case $k$ is odd and $k$-approximately magic in case $k$ is even.

Recall that the Cartesian product $G_{1} \times G_{2}$ of two graphs $G_{1}=\left(V_{1}, E_{1}\right)$ and $G_{2}=\left(V_{2}, E_{2}\right)$ is a graph with vertex set $V_{1} \times V_{2}$, and $\left(u_{1}, u_{2}\right)$ is adjacent to $\left(v_{1}, v_{2}\right)$ in $G_{1} \times G_{2}$ if and only if $u_{1}=v_{1}$ and $u_{2} v_{2} \in E_{2}$, or, $u_{2}=v_{2}$ and $u_{1} v_{1} \in E_{1}$.

Using the approximate magicness results in Theorem 1.1, we prove the following theorem in Section 3.
Theorem 1.2. If $G_{1}$ is an $n_{1}$-vertex $k_{1}$-regular connected graph, and $G_{2}$ is a graph (not necessarily connected) with maximum degree at most $k_{2}$, minimum degree at least one, then $G_{1} \times G_{2}$ is antimagic, provided that $k_{1}$ is odd and $\frac{k_{1}^{2}-k_{1}}{2} \geq k_{2}$, or, $k_{1}$ is even and $\frac{k_{1}^{2}}{2} \geq k_{2}$ and $k_{1}, k_{2}$ are not both equal to 2 .

By combining Theorem 1.2 and the antimagicness result on the Cartesian products of two cycles in [7], the following theorem is obtained in Section 4.

Theorem 1.3. All Cartesian products of two or more regular graphs of positive degree are antimagic.
Finally, we give a generalization of Theorem 1.1 in which $G$ is not necessarily connected, and a generalization of Theorem 1.2 in which $G_{1}$ is not necessarily connected. The following two theorems are proved in Section 5.

Theorem 1.4 (Generalization of Theorem 1.1). If $G$ is an $n$-vertex $k$-regular graph ( $k \geq 1, G$ is not necessarily connected), then $G$ is $\left(\frac{n k}{2}-1\right)$-approximately magic in case $k$ is odd and $\left(\frac{2 n}{3}+k-1\right)$-approximately magic in case $k$ is even.

Theorem 1.5 (Generalization of Theorem 1.2). If $G_{1}$ is an $n_{1}$-vertex $k_{1}$-regular graph, and $G_{2}$ is a graph with maximum degree at most $k_{2}$, minimum degree at least one ( $G_{1}, G_{2}$ are not necessarily connected), then $G_{1} \times G_{2}$ is antimagic, provided that $k_{1}$ is odd and $\frac{k_{1}^{2}-k_{1}}{2} \geq k_{2}$, or, $k_{1}$ is even and $\frac{k_{1}^{2}}{2}>k_{2}$.

For more results, open problems and conjectures on magic graphs, antimagic graphs and various graph labeling problems, please see [4].

Throughout the paper, we denote $\lceil x\rceil$ (ceiling of $x$ ) to be the least integer that is not less than $x$, denote $\lfloor x\rfloor$ (floor of $x$ ) to be the largest integer that is not greater than $x$.

## 2. Proof of Theorem 1.1

We begin with some terms and definitions (see [5]). A walk in a graph $G$ is an alternating sequence $v_{1} e_{1} v_{2} e_{2} \cdots e_{t-1} v_{t}$ of vertices and edges of $G$, with the property that every edge $e_{i}$ is incident with $v_{i}$ and $v_{i+1}$, for $i=1, \ldots, t-1$. Vertices and edges may be repeated in a walk. A trail in a graph $G$ is a walk in $G$ with the property that no edge is repeated. A circuit is a closed trail, that is a trail whose endpoints are the same vertex. A cycle is a circuit with the property that no vertex is repeated. An Eulerian circuit in a graph $G$ is a circuit that contains every edge of $G$. In order to prove Theorem 1.1 for the case that $k$ is odd, we need the following theorem ([5], pp. 56),

$m=2 p$

$m=2 p+1$

Fig. 1. Labeling of the sequence of trails $T: t_{1} t_{2} \ldots t \frac{n}{2}$.
Theorem 2.1 (Part of Listing Theorem). If $G$ is a connected graph with precisely $2 h$ vertices of odd degree, $h \neq 0$, then there exist $h$ trails in $G$ such that each edge of $G$ is in exactly one of these trails.

If $G$ is a connected $n$-vertex regular graph of odd degree $k$, by Theorem 2.1, there are $n / 2$ trails $t_{1}, t_{2}, \ldots, t_{\frac{n}{2}}$ in $G$, such that each edge of $G$ is in exactly one of these trails. Denote $|t|$ to be the length (number of edges) of a trail $t$. Without loss of generality, assume that $\left|t_{1}\right| \geq\left|t_{2}\right| \geq \cdots \geq\left|t_{\frac{n}{2}}\right|$. By concatenating these trails we get a sequence $T: t_{1} t_{2} \ldots t_{\frac{n}{2}}$, which contains all the $m\left(=\frac{n k}{2}\right)$ edges of $G$. Number the edges of $G$ according to their ordering in $T$, let $e_{1}, e_{2}, \ldots, e_{m}$ be the numbering. Assign the labels $1,2, \ldots,\left\lceil\frac{m}{2}\right\rceil$ to the edges of odd indices $e_{1}, e_{3}, \ldots$ etc., and assign the labels $m, m-1, \ldots,\left\lceil\frac{m}{2}\right\rceil+1$ to the edges of even indices $e_{2}, e_{4}, \ldots$ etc. (see Fig. 1). It is easy to see that for the above labeling, the sum of any two consecutive edges in $T$ is either $m+1$ or $m+2$. In addition, if $e$ is the first or the last edge of a trail, then the largest possible label received by $e$ is at most $m-\frac{k-1}{2}$ (notice that $\left|t_{1}\right| \geq k$ ). For each vertex $v$ of $G$, the $k$ edges incident with $v$ can be partitioned into $\frac{k-1}{2}$ pairs and a singleton, such that each pair is composed of two consecutive edges within one of the above $n / 2$ trails, and the single edge is the first or the last edge of a trail. Therefore, for the above labeling, the sum received by any vertex of $G$ is at most $\left(m-\frac{k-1}{2}\right)+\frac{k-1}{2} \times(m+2)=m+\frac{k-1}{2} \times(m+1)$, at least $1+\frac{k-1}{2} \times(m+1)$, implying that this is an $\left(\frac{n k}{2}-1\right)$-approximately magic labeling of $G$. For the case that the degree $k$ is even, we need the following lemma.

Lemma 2.2. Every m-vertex connected regular graph of degree 2 (i.e., cycle $C_{m}$ ) is 2-approximately magic, for $m \geq 3$.

Proof. We have the following four cases:
Case $1 . m \equiv 1(\bmod 4)$. Let $m=4 t+1, t \geq 1$. Partition the labels $1,2, \ldots, m$ into $2 t+1$ groups (1), $(2,3), \ldots,(2 t, 2 t+1),(2 t+2,2 t+3), \ldots,(m-1, m)$. First assign label 1 to an arbitrary edge of $C_{m}$, then assign the labels $(m, m-1),(2,3),(m-2, m-3),(4,5), \ldots,(2 t, 2 t+1)$ in a way that each pair of labels is assigned to the two edges that have common endpoints with the labeled arc.
Case $2 . m \equiv 3(\bmod 4)$. Let $m=4 t+3, t \geq 0$. Partition the labels $1,2, \ldots, m$ into $2 t+2$ groups (1), $(2,3), \ldots,(2 t, 2 t+1),(2 t+2,2 t+3), \ldots,(m-1, m)$. First assign label 1 to an arbitrary edge of $C_{m}$, then assign the labels $(m, m-1),(2,3),(m-2, m-3),(4,5), \ldots,(2 t+3,2 t+2)$ in the same way as in Case 1 .
Case 3. $m \equiv 0(\bmod 4)$. Let $m=4 t+4, t \geq 0$. Partition the labels $1,2, \ldots, m$ into $2 t+3$ groups (1), $(2,3), \ldots,(2 t, 2 t+1),(2 t+2),(2 t+3,2 t+4), \ldots,(m-1, m)$. First assign label 1 to an arbitrary edge of $C_{m}$, then assign the labels $(m, m-1),(2,3),(m-2, m-3),(4,5), \ldots,(2 t+4,2 t+3)$ in the way that each pair of labels are assigned to the two edges that have common endpoints with the labeled arc, finally assign the label $2 t+2$ to the one non-labeled edge.
Case 4. $m \equiv 2(\bmod 4)$. Let $m=4 t+2, t \geq 1$. Partition the labels $1,2, \ldots, m$ into $2 t+2$ groups (1), $(2,3), \ldots,(2 t, 2 t+1),(2 t+2),(2 t+3,2 t+4), \ldots,(m-1, m)$. First assign label 1 to an arbitrary edge of $C_{m}$, then assign the labels $(m, m-1),(2,3),(m-2, m-3),(4,5), \ldots,(2 t, 2 t+1),(2 t+2)$ in the same way as in Case 3.

It is easy to see that in any of the above cases, the vertex sums of $C_{m}$ are all among $m, m+1$, and $m+2$, implying the assertion of the lemma (see Fig. 2).

Recall that a connected graph with all vertices of even degrees has an Eulerian circuit. It follows that if $G$ is a connected $n$-vertex regular graph of even degree $k, G$ has an Eulerian circuit, without loss of generality, say $e_{1} e_{2} \ldots e_{m}$, where $m=\frac{n k}{2}$. We label $1,2, \ldots, m$ to this circuit using the above 2 -approximately magic labeling in Lemma 2.2 (here we view this circuit as a cycle). For each vertex $v$ of $G$, the $k$ edges incident with $v$ can be

Fig. 2. 2-Approximately magic labeling of $C_{m}$.
partitioned into $k / 2$ pairs such that each pair is composed of two consecutive edges in the Eulerian circuit $e_{1} e_{2} \ldots e_{m}$, thus the sum of each pair is among $m, m+1$, and $m+2$. Therefore, for the above labeling, the sum received by any vertex of $G$ is at least $\frac{k}{2} \times m$, at most $\frac{k}{2} \times(m+2)$, implying that the labeling of $G$ is $k$-approximately magic.

## 3. Proof of Theorem 1.2

Suppose that $G_{1}$ is an $n_{1}$-vertex $k_{1}$-regular connected graph, $V\left(G_{1}\right)=\left\{u_{1}, u_{2}, \ldots, u_{n_{1}}\right\}$, and $G_{2}$ is a graph with maximum degree at most $k_{2}$, minimum degree at least one, $V\left(G_{2}\right)=\left\{v_{1}, v_{2}, \ldots, v_{n_{2}}\right\}$. Denote by $m_{1}\left(=\frac{k_{1} n_{1}}{2}\right)$ and $m_{2}$ the number of edges of $G_{1}$ and $G_{2}$, respectively.

Let $f: E\left(G_{1} \times G_{2}\right) \rightarrow\left\{1,2, \ldots, m_{2} n_{1}+m_{1} n_{2}\right\}$ be an edge labeling of $G_{1} \times G_{2}$, and denote the induced sum at vertex $(u, v)$ by $w(u, v)=\sum f((u, v),(y, z))$, where the sum runs over all vertices $(y, z)$ adjacent to $(u, v)$ in $G_{1} \times G_{2}$. In the product graph $G_{1} \times G_{2}$, at each vertex $(u, v)$, the edges incident to this vertex can be partitioned into two parts, one part is contained in a copy of $G_{1}$ component, and the other part is contained in a copy of $G_{2}$ component. Denote by $w_{1}(u, v)$ and $w_{2}(u, v)$ the sum at vertex $(u, v)$ restricted to $G_{1}$ component and $G_{2}$ component respectively, i.e., $w_{1}(u, v)=\sum f((u, v),(y, v))$, where the sum runs over all vertices $y$ adjacent to $u$ in $G_{1}$, and $w_{2}(u, v)=\sum f((u, v),(u, z))$, where the sum runs over all vertices $z$ adjacent to $v$ in $G_{2}$. Therefore, $w(u, v)=w_{1}(u, v)+w_{2}(u, v)$.

Given two isomorphic graphs $G$ and $G^{\prime}$, and two labelings $f$ and $f^{\prime}$ of $G$ and $G^{\prime}$ respectively, we call $f^{\prime}$ a $\delta$-shift of $f$, if for each edge $e \in E(G)$ and its counterpart $e^{\prime} \in E\left(G^{\prime}\right)$ under the isomorphism, we have $f^{\prime}\left(e^{\prime}\right)=f(e)+\delta$. Now we will present our labeling of $G_{1} \times G_{2}$, which contains two steps.
Step 1 (renaming vertices): Assign labels $1,2, \ldots, m_{1}$ to the edges of $G_{1}$, such that the labeling is $\left(\frac{n_{1} k_{1}}{2}-1\right)$ approximately magic if $k_{1}$ is odd, $k_{1}$-approximately magic if $k_{1}$ is even. Without loss of generality, we can rename the vertices of $G_{1}$ such that $w\left(u_{1}\right) \leq w\left(u_{2}\right) \leq \cdots \leq w\left(u_{n_{1}}\right)$, denote this labeling by $L_{1}$. Assign labels $1, n_{1}+1,2 n_{1}+1, \ldots,\left(m_{2}-1\right) n_{1}+1$ arbitrarily to the edges of $G_{2}$. Similarly, rename the vertices of $G_{2}$ such that $w\left(v_{1}\right) \leq w\left(v_{2}\right) \leq \cdots \leq w\left(v_{n_{2}}\right)$, denote this labeling by $L_{2}$.
Step 2 (labeling $G_{1} \times G_{2}$ ): Assign labels $m_{2} n_{1}+1, m_{2} n_{1}+2, \ldots, m_{2} n_{1}+m_{1} n_{2}$ to the edges that are contained in copies of $G_{1}$ component. For the $i$ th $G_{1}$ component (with vertices $\left(u_{1}, v_{i}\right),\left(u_{2}, v_{i}\right), \ldots,\left(u_{n_{1}}, v_{i}\right)$ ), label its edges with $m_{2} n_{1}+(i-1) m_{1}+1, m_{2} n_{1}+(i-1) m_{1}+2, \ldots, m_{2} n_{1}+(i-1) m_{1}+m_{1}$, such that the labeling is an [ $\left.m_{2} n_{1}+(i-1) m_{1}\right]$-shift of $L_{1}$, under the natural isomorphism, for $i=1, \ldots, n_{2}$. Since $G_{1}$ is regular, we have $w_{1}\left(u_{1}, v_{i}\right) \leq w_{1}\left(u_{2}, v_{i}\right) \leq \cdots \leq w_{1}\left(u_{n_{1}}, v_{i}\right)$, for $i=1, \ldots, n_{2}$.

Assign labels $1,2, \ldots, m_{2} n_{1}$ to the edges that are contained in copies of $G_{2}$ component. For the $j$ th $G_{2}$ component (with vertices $\left.\left(u_{j}, v_{1}\right),\left(u_{j}, v_{2}\right), \ldots,\left(u_{j}, v_{n_{2}}\right)\right)$, label its edges with $j, n_{1}+j, 2 n_{1}+j, \ldots,\left(m_{2}-1\right) n_{1}+j$, such that the labeling is a $(j-1)$-shift of $L_{2}$, under the natural isomorphism, for $j=1, \ldots, n_{1}$. From the way we name the vertices of $G_{2}$, we have $w_{2}\left(u_{1}, v_{1}\right) \leq w_{2}\left(u_{1}, v_{2}\right) \leq \cdots \leq w_{2}\left(u_{1}, v_{n_{2}}\right)$.

In what follows we will prove that for the above labeling, if $k_{1}$ is odd and $\frac{k_{1}^{2}-k_{1}}{2} \geq k_{2}$, or, if $k_{1}$ is even and $\frac{k_{1}^{2}}{2} \geq k_{2}$ and $k_{1}, k_{2}$ are not both equal to 2 , then

$$
\begin{aligned}
& w\left(u_{1}, v_{1}\right)<w\left(u_{2}, v_{1}\right)<\ldots \ldots \ldots \ldots<w\left(u_{n_{1}}, v_{1}\right)< \\
& w\left(u_{1}, v_{2}\right)<w\left(u_{2}, v_{2}\right)<\cdots \ldots \ldots \ldots .<w\left(u_{n_{1}}, v_{2}\right)< \\
& w\left(u_{1}, v_{n_{2}}\right)<w\left(u_{2}, v_{n_{2}}\right)<\cdots \cdots \cdots \cdots<w\left(u_{n_{1}}, v_{n_{2}}\right),
\end{aligned}
$$

implying that the above labeling is antimagic.

For each $i \in\left\{1, \ldots, n_{2}\right\}$, we have $w_{1}\left(u_{1}, v_{i}\right) \leq w_{1}\left(u_{2}, v_{i}\right) \leq \cdots \leq w_{1}\left(u_{n_{1}}, v_{i}\right)$, and $w_{2}\left(u_{1}, v_{i}\right)<w_{2}\left(u_{2}, v_{i}\right)<$ $\cdots<w_{2}\left(u_{n_{1}}, v_{i}\right)$ since $w_{2}\left(u_{j+1}, v_{i}\right)-w_{2}\left(u_{j}, v_{i}\right)=d\left(v_{i}\right)$, where $d\left(v_{i}\right) \geq 1$ is the degree of $v_{i}$ in $G_{2}$, $j=1, \ldots, n_{1}-1$. It follows that $w\left(u_{1}, v_{i}\right)<w\left(u_{2}, v_{i}\right)<\cdots<w\left(u_{n_{1}}, v_{i}\right)$, for $i=1, \ldots, n_{2}$. In order to prove $w\left(u_{1}, v_{i+1}\right)>w\left(u_{n_{1}}, v_{i}\right)$, for $i=1, \ldots, n_{2}-1$, we distinguish between two cases.
Case 1. $k_{1}$ is odd. For each $i \in\left\{1, \ldots, n_{2}-1\right\}$, we have $w\left(u_{1}, v_{i+1}\right) \geq w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ since $w_{1}\left(u_{1}, v_{i+1}\right)=$ $w_{1}\left(u_{1}, v_{i}\right)+m_{1} k_{1}=w_{1}\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ (notice that the labeling of the $(i+1)$ th $G_{1}$ component is an $m_{1}$-shift of the labeling of the $i$ th $G_{1}$ component) and $w_{2}\left(u_{1}, v_{i+1}\right) \geq w_{2}\left(u_{1}, v_{i}\right)$. In addition, we have $w\left(u_{n_{1}}, v_{i}\right) \leq w\left(u_{1}, v_{i}\right)+$ $\left(\frac{n_{1} k_{1}}{2}-1\right)+k_{2}\left(n_{1}-1\right)$ since $w_{1}\left(u_{n_{1}}, v_{i}\right) \leq w_{1}\left(u_{1}, v_{i}\right)+\left(\frac{n_{1} k_{1}}{2}-1\right)$ (notice that $G_{1}$ is regular and $L_{1}$ is $\left(\frac{n_{1} k_{1}}{2}-1\right)-$ approximately magic when $k_{1}$ is odd), and $w_{2}\left(u_{n_{1}}, v_{i}\right)=w_{2}\left(u_{1}, v_{i}\right)+d\left(v_{i}\right)\left(n_{1}-1\right) \leq w_{2}\left(u_{1}, v_{i}\right)+k_{2}\left(n_{1}-1\right)$. It follows that $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq\left(w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}\right)-\left(w\left(u_{1}, v_{i}\right)+\left(\frac{n_{1} k_{1}}{2}-1\right)+k_{2}\left(n_{1}-1\right)\right)=$ $n_{1}\left(\frac{k_{1}^{2}-k_{1}}{2}-k_{2}\right)+1+k_{2}>0$, for $i=1, \ldots, n_{2}-1$.
Case 2. $k_{1}$ is even. Similarly, for each $i \in\left\{1, \ldots, n_{2}-1\right\}$, we have $w\left(u_{1}, v_{i+1}\right) \geq w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ since $w_{1}\left(u_{1}, v_{i+1}\right)=w_{1}\left(u_{1}, v_{i}\right)+m_{1} k_{1}=w_{1}\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ and $w_{2}\left(u_{1}, v_{i+1}\right) \geq w_{2}\left(u_{1}, v_{i}\right)$. In addition, $w\left(u_{n_{1}}, v_{i}\right) \leq$ $w\left(u_{1}, v_{i}\right)+k_{1}+k_{2}\left(n_{1}-1\right)$ holds since $w_{1}\left(u_{n_{1}}, v_{i}\right) \leq w_{1}\left(u_{1}, v_{i}\right)+k_{1}$ ( $L_{1}$ is $k_{1}$-approximately magic when $k_{1}$ is even) and $w_{2}\left(u_{n_{1}}, v_{i}\right)=w_{2}\left(u_{1}, v_{i}\right)+d\left(v_{i}\right)\left(n_{1}-1\right) \leq w_{2}\left(u_{1}, v_{i}\right)+k_{2}\left(n_{1}-1\right)$. It follows that $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq$ $\left(w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}\right)-\left(w\left(u_{1}, v_{i}\right)+k_{1}+k_{2}\left(n_{1}-1\right)\right)=n_{1}\left(\frac{k_{1}^{2}}{2}-k_{2}\right)+k_{2}-k_{1}$.

If $\frac{k_{1}^{2}}{2}>k_{2}$, since $k_{1}$ is even, $\frac{k_{1}^{2}}{2}-k_{2} \geq 1$, then $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq n_{1}\left(\frac{k_{1}^{2}}{2}-k_{2}\right)+k_{2}-k_{1} \geq$ $n_{1}+k_{2}-k_{1}>0$ (since $n_{1}>k_{1}$ ). If $\frac{k_{1}^{2}}{2}=k_{2}$, since $k_{1}, k_{2}$ are not both equal to 2 , we have $k_{1}>2$, it follows that $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq k_{2}-k_{1}=\frac{k_{1}^{2}}{2}-k_{1}>0$. Thus, in any case, we have $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right)>0$, for $i=1, \ldots, n_{2}-1$.

Therefore, (1) holds, implying the assertion of Theorem 1.2.

## 4. Proof of Theorem 1.3

Since the Cartesian product preserves regularity, we only need to prove that all Cartesian products of two regular graphs are antimagic. We first prove Theorem 1.3 for the case that $G_{1}$ and $G_{2}$ are both connected, then we generalize the proof to the case where $G_{1}$ and $G_{2}$ are not necessarily connected.

### 4.1. Connected case

Suppose that $G_{1}$ is an $n_{1}$-vertex $k_{1}$-regular connected graph, and $G_{2}$ is an $n_{2}$-vertex $k_{2}$-regular connected graph. Without loss of generality, assume that $k_{1} \geq k_{2}$. Furthermore, we may assume $k_{1} \geq 2$ since $K_{2} \times K_{2}$ can be easily verified as antimagic. If $k_{1}=2$ and $k_{2}=1$, by Theorem $1.2, G_{1} \times G_{2}$ is antimagic. If $k_{1}=2$ and $k_{2}=2$, then $G_{1} \times G_{2}$ is a toroidal grid graph and its antimagicness is proved in [7]. For $k_{1} \geq 3$, if $k_{1}$ is odd, then $\frac{k_{1}^{2}-k_{1}}{2} \geq k_{1} \geq k_{2}$; if $k_{1}$ is even, then $k_{1} \geq 4, \frac{k_{1}^{2}}{2}>k_{1} \geq k_{2}$. Thus by Theorem $1.2, G_{1} \times G_{2}$ is antimagic.

### 4.2. Unconnected case

Denote by $c_{1}$ and $c_{2}$ the numbers of connected components of $G_{1}$ and $G_{2}$, respectively. It is easy to see that the number of connected components of $G_{1} \times G_{2}$ is $c=c_{1} \times c_{2}$, and each of its connected components is a $\left(k_{1}+k_{2}\right)$ regular graph (which is the product of one $k_{1}$-regular connected graph and one $k_{2}$-regular connected graph). Let $m_{1}, m_{2}, \ldots, m_{c}$ be the numbers of edges of these connected components $C_{1}, C_{2}, \ldots, C_{c}$. The labeling of $G_{1} \times G_{2}$ goes as follows. Assign $1,2, \ldots, m_{1}$ to the edges of $C_{1}$, assign $m_{1}+1, m_{1}+2, \ldots, m_{1}+m_{2}$ to the edges of $C_{2}, \ldots \ldots$, and assign $m_{1}+\cdots+m_{c-1}+1, m_{1}+\cdots+m_{c-1}+2, \ldots, m_{1}+\cdots+m_{c-1}+m_{c}$ to the edges of $C_{c}$, such that the labeling of each connected component is antimagic (this can be achieved because of the previous proof for the case where $G_{1}$ and $G_{2}$ are both connected and the regularity of each component). The whole labeling of $G_{1} \times G_{2}$ is antimagic, since between any two different components, any sum of $k_{1}+k_{2}$ labels from a group of larger labels must be greater than any sum of $k_{1}+k_{2}$ labels from a group of smaller labels.

## 5. Generalizations of Theorems 1.1 and 1.2

In this section, we will prove Theorem 1.4, a generalization of Theorem 1.1 in which $G$ is not necessarily connected, and Theorem 1.5, a generalization of Theorem 1.2 in which $G_{1}$ is not necessarily connected.

### 5.1. Proof of Theorem 1.4

For the case $k$ is odd, by Theorem 2.1 (Listing), for each connected component of $G$ (which is a connected $k$-regular graph), if it has $n_{i}$ vertices, we can decompose it into $\frac{n_{i}}{2}$ trails. By running this decomposition over all connected components of $G$, we can get a total number of $\frac{n}{2}$ trails, such that each edge of $G$ is in exactly one of these trails. It is easy to see that the largest length of these trails is at least $k$. We concatenate these trails into a sequence in the ordering of non-increasing lengths, and label the sequence in the same way as in Theorem 1.1, which results in an $\left(\frac{n k}{2}-1\right)$-approximately magic labeling of $G$. For the case $k$ is even, we first prove the following lemma.

Lemma 5.1. If $G$ is an n-vertex graph consisting of vertex-disjoint cycles of odd sizes (numbers of edges), then $G$ is $\left\lceil\frac{2 n}{3}\right\rceil$-approximately magic, for $n \geq 3$.

Proof. Suppose that $G$ is composed of $l$ cycles $C_{1}, C_{2}, \ldots, C_{l}$ (of sizes $n_{1}, n_{2}, \ldots, n_{l}$, where $n_{1} \geq n_{2} \geq \cdots \geq n_{l} \geq 3$ are odd numbers, and $n_{1}+\cdots+n_{l}=n$ ). Let $n=3 t+\varepsilon, t \geq 1, \varepsilon \in\{0,1,2\}$. We partition the labels $1, \ldots, n$ into three groups $1,2, \ldots, t$ and $t+1, \ldots, 2 t+\varepsilon$ and $2 t+\varepsilon+1,2 t+\varepsilon+2, \ldots, 3 t+\varepsilon$. Let $A: a_{1}, a_{2}, \ldots, a_{t}$ denote the sequence $1,2, \ldots, t$; let $B: b_{1}, b_{2}, \ldots, b_{t+\varepsilon}$ denote the sequence $2 t+\varepsilon, 2 t+\varepsilon-1, \ldots, t+1$; and let $C: c_{1}, c_{2}, \ldots, c_{t}$ denote the sequence $2 t+\varepsilon+1,2 t+\varepsilon+2, \ldots, 3 t+\varepsilon$. It is easy to see that $2 t+\varepsilon+2 \leq a_{i}+c_{j} \leq 4 t+\varepsilon, a_{i}+b_{i}=2 t+\varepsilon+1$, and $b_{i}+c_{i}=4 t+2 \varepsilon+1$, for $i, j=1,2, \ldots, t$. In addition, $2 t+3 \leq b_{i}+b_{j} \leq 4 t+2 \varepsilon-1$, for $i \neq j, i, j=1,2, \ldots, t$.

Let $m_{i}=\frac{n_{i}-1}{2}, i=1,2, \ldots, l$. We will present a labeling of $G$, which goes as follows. Label the cycles $C_{1}, C_{2}, \ldots, C_{l}$ one by one. For the $i$ th cycle $C_{i}$, pick the $m_{i}$ smallest elements from the current (remained) $A$ sequence and the $m_{i}$ smallest elements from the current (remained) $C$-sequence, if at this moment there are at least $m_{i}$ elements remained in $A$ (also $C$ ). Otherwise, pick all the remained elements of the two sequences. Specifically, we have the following two cases.
Case 1. At the beginning of the labeling of $C_{i}$, there are at least $m_{i}$ elements remained in the current $A$ - (also $C$-) sequence. Denote by $a_{s_{i}+1}, a_{s_{i}+2}, \ldots, a_{s_{i}+m_{i}}$ and $c_{s_{i}+1}, c_{s_{i}+2}, \ldots, c_{s_{i}+m_{i}}$ (where $s_{1}=0$, and $s_{i}=m_{1}+\cdots+m_{i-1}$ for $1<i \leq l$ ) the $m_{i}$ smallest elements of the current $A$ - (and $C$-) sequence. Pick $b_{s_{i}+m_{i}}$ from the current $B$-sequence, and label the edges of $C_{i}$ sequentially with $b_{s_{i}+m_{i}}, c_{s_{i}+1}, a_{s_{i}+1}, c_{s_{i}+2}, a_{s_{i}+2}, \ldots, c_{s_{i}+m_{i}}, a_{s_{i}+m_{i}}$, then remove these elements from their sequences. Since $3 t+\varepsilon+2 \leq b_{s_{i}+m_{i}}+c_{s_{i}+1} \leq 4 t+2 \varepsilon+1$, for the above labeling, each vertex sum of $C_{i}$ is at least $2 t+\varepsilon+1$, and at most $4 t+2 \varepsilon+1$.
Case 2. At the beginning of the labeling of $C_{i}$, the number of elements remained in the current $A$ - (also $C$-) sequence is less than $m_{i}$. In this case we must have $n_{1} \geq 5$ (otherwise all cycles are 'triangles', i.e. consisting of 3 edges, in our labeling each triangle will be labeled by three elements, and exactly one element from each sequence, which is a contradiction). We can assume that $l \geq 2$, since for the case $l=1 G$ has been proved to be 2 -approximately magic in Lemma 2.2.

If the current $A$-(also $C$-) sequence is empty, then label the remained non-labeled cycles arbitrarily using elements remained in $B$-sequence. Otherwise, pick all the elements $a_{s_{i}+1}, a_{s_{i}+2}, \ldots, a_{t}$ and $c_{s_{i}+1}, c_{s_{i}+2}, \ldots, c_{t}$ from the current $A$ - and $C$-sequences. At this moment, besides $b_{t}$ (where $t \geq 2$ since $l \geq 2$ ), $b_{1}$ is unused (if $i=1$, since $t \geq 2$, we have $b_{1}$ distinct from $b_{t}$ and unused; if $i>1$, since $n_{1} \geq 5, b_{1}$ has not been used for labeling $C_{1}$, thus is unused). Remove $b_{t}$ and $b_{1}$ from the current $B$-sequence, and label the elements $b_{t}, c_{s_{i}+1}, a_{s_{i}+1}, c_{s_{i}+2}, a_{s_{i}+2}, \ldots, c_{t}, a_{t}, b_{1}$ sequentially to an arc of consecutive edges of $C_{i}$. Then, label the remained non-labeled edges of $C_{i}$ using arbitrary elements remained in $B$-sequence, and remove these elements from $B$. Since $3 t+\varepsilon+2 \leq b_{t}+c_{s_{i}+1} \leq 4 t+2 \varepsilon+1$, and $a_{t}+b_{1}=3 t+\varepsilon$, we have that for the above labeling, each vertex sum of $C_{i}$ is at least $2 t+\varepsilon+1$, and at most $4 t+2 \varepsilon+1$.

Therefore, for the above labeling, the vertex sums of $G$ are at least $2 t+\varepsilon+1$ (which is $\left\lceil\frac{2 n}{3}\right\rceil+1$ ), at most $4 t+2 \varepsilon+1$ (which is $2\left\lceil\frac{2 n}{3}\right\rceil+1$ ), implying that the differences between vertex sums of $G$ are at most $\left\lceil\frac{2 n}{3}\right\rceil$.

Remark 5.2. The result that $G$ is $\left\lceil\frac{2 n}{3}\right\rceil$-approximately magic in Lemma 5.1 is actually asymptotically best possible. Consider the case of $G$ consisting of $\frac{n}{3}$ 'triangles'. Suppose that label 1 is assigned to an edge $v_{1} v_{2}$ of a triangle $v_{1} v_{2} v_{3}$, if the edge $v_{2} v_{3}$ or $v_{1} v_{3}$ is assigned with a label $l>\frac{2 n}{3}$, then the difference of the two vertex sums of $v_{3}$ and $v_{1}$, or $v_{3}$ and $v_{2}$ will be at least $\frac{2 n}{3}$. Similarly, suppose that label $n$ is assigned to an edge $v_{4} v_{5}$ of a triangle $v_{4} v_{5} v_{6}$, if the edge $v_{4} v_{6}$ or $v_{5} v_{6}$ is assigned with a label $l \leq \frac{n}{3}$, then the difference of the two vertex sums of $v_{5}$ and $v_{6}$, or $v_{4}$ and $v_{6}$ will be at least $\frac{2 n}{3}$. If neither of the above two cases happens, then the vertex sum of $v_{1}$ or $v_{2}$ is at most $\frac{2 n}{3}+1$, and the vertex sum of $v_{4}$ is at least $\frac{4 n}{3}+1$, thus, the difference of the two vertex sums of $v_{4}$ and $v_{1}$, or $v_{4}$ and $v_{2}$ is at least $\frac{2 n}{3}$.

Now we will prove Theorem 1.4 for the case that $k$ is even. Since $k$ is even, $G$ is an even graph (a graph with all vertices having even degrees), it follows that $G$ can be decomposed into edge-disjoint simple cycles. In addition, two cycles having a common vertex can be merged into one circuit. Therefore, by repeating the merging of two cycles of odd sizes that have a common vertex into an even circuit, finally we will obtain a collection of $s(\geq 0)$ even circuits $P_{1}, P_{2}, \ldots, P_{s}$ (of sizes $2 m_{1}, 2 m_{2}, \ldots, 2 m_{s}$ ), together with a collection of $t(\geq 0)$ vertex-disjoint odd cycles $Q_{1}, Q_{2}, \ldots, Q_{t}$ (of sizes $n_{1}, n_{2}, \ldots, n_{t}$, and $n_{1}+n_{2}+\cdots+n_{t} \leq n$ ), such that each edge of $G$ is in exactly one of these circuits or cycles.

Let $m=\frac{n k}{2}$ be the number of edges of $G$. First we label the even circuits $P_{1}, P_{2}, \ldots, P_{s}$. By viewing these circuits as cycles, using the 2 -approximately magic labeling in Lemma 2.2 , we assign labels $1,2, \ldots, m_{1}$ and $m, m-1, \ldots, m-m_{1}+1$ to $P_{1}$, assign labels $m_{1}+1, m_{1}+2, \ldots, m_{1}+m_{2}$ and $m-m_{1}, m-m_{1}-1, \ldots, m-m_{1}-m_{2}+1$ to $P_{2}, \ldots \ldots$, and assign labels $m_{1}+\cdots+m_{s-1}+1, m_{1}+\cdots+m_{s-1}+2, \ldots \ldots, m_{1}+\cdots+m_{s-1}+m_{s}$ and $m-m_{1}-\cdots-m_{s-1}, m-m_{1}-\cdots-m_{s-1}-1, \ldots \ldots, m-m_{1}-\cdots-m_{s-1}-m_{s}+1$ to $P_{s}$. Thus, the sum of any two consecutive edges of circuit $P_{i}(i=1, \ldots, s)$ is among $m, m+1$, and $m+2$.

Let $m^{*}=m_{1}+m_{2}+\cdots+m_{s}$, and $n^{*}=n_{1}+n_{2}+\cdots+n_{t}$. If $n^{*}=0$ (i.e., there is no odd cycle), similarly as in Theorem 1.1, the above labeling of $G$ can be proved to be $k$-approximately magic, by partitioning the $k$ edges incident with any vertex of $G$ into $k / 2$ pairs such that each pair is composed of two consecutive edges in some circuit $P_{i}(i \in$ $\{1, \ldots, s\})$. Otherwise, we have $n^{*} \geq 3$. Assign the remained labels $m^{*}+1, m^{*}+2, \ldots, m^{*}+n^{*}$ to the vertex-disjoint odd cycles $Q_{1}, Q_{2}, \ldots, Q_{t}$, using the $\left\lceil\frac{2 n^{*}}{3}\right\rceil$-approximately magic labeling in Lemma 5.1. Since $2 m^{*}+n^{*}=m$, and $\left\lfloor\frac{n^{*}}{3}\right\rfloor+\left\lceil\frac{2 n^{*}}{3}\right\rceil=n^{*}$ for all integers $n^{*} \geq 1$, it follows that the sum of any two consecutive edges of these odd cycles is at least $2 m^{*}+\left\lceil\frac{2 n^{*}}{3}\right\rceil+1=m+1-\left\lfloor\frac{n^{*}}{3}\right\rfloor(\leq m)$, and at most $2 m^{*}+2\left\lceil\frac{2 n^{*}}{3}\right\rceil+1=m+1-\left\lfloor\frac{n^{*}}{3}\right\rfloor+\left\lceil\frac{2 n^{*}}{3}\right\rceil(\geq m+2)$. Therefore, for the whole labeling of $G$, the sum received by any vertex of $G$ is at least $m \times \frac{k-2}{2}+\left(m+1-\left\lfloor\frac{n^{*}}{3}\right\rfloor\right)$, at most $(m+2) \times \frac{k-2}{2}+\left(m+1-\left\lfloor\frac{n^{*}}{3}\right\rfloor+\left\lceil\frac{2 n^{*}}{3}\right\rceil\right)$. Since $n^{*} \leq n$, the whole labeling of $G$ is $\left(\frac{2 n}{3}+k-1\right)$-approximately magic.

### 5.2. Proof of Theorem 1.5

If $k_{1}=2$, since $\frac{k_{1}^{2}}{2}>k_{2}, k_{2}=1, G_{2}$ is 1-regular, by Theorem 1.3, $G_{1} \times G_{2}$ is antimagic. In what follows we assume that $k_{1} \geq 3$.

We do the same labeling on $G_{1} \times G_{2}$ as in Theorem 1.2 (when $k_{1}$ is even, the labeling $L_{1}$ on $G_{1}$ here is ( $\frac{2 n_{1}}{3}+k_{1}-1$ )approximately magic). We will prove that for this labeling, (1) still holds if $k_{1} \geq 3$ is odd and $\frac{k_{1}^{2}-k_{1}}{2} \geq k_{2}$, or, if $k_{1} \geq 4$ is even and $\frac{k_{1}^{2}}{2}>k_{2}$.
$w\left(u_{1}, v_{i}\right)<w\left(u_{2}, v_{i}\right)<\cdots<w\left(u_{n_{1}}, v_{i}\right)$ can be proved by using the same argument in Theorem 1.2, for $i=1, \ldots, n_{2}$. In order to prove $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right)>0$, for $i=1, \ldots, n_{2}-1$, there are two cases.

Case $1 . k_{1}$ is odd. Since $G_{1}$ is still $\left(\frac{n_{1} k_{1}}{2}-1\right)$-approximately magic, by using the same argument in Theorem 1.2, we can obtain that $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right)>0$, for $i=1, \ldots, n_{2}-1$.

Case 2. $k_{1}$ is even (thus $k_{1} \geq 4$ ). $G_{1}$ is ( $\frac{2 n_{1}}{3}+k_{1}-1$ )-approximately magic. For each $i \in\left\{1, \ldots, n_{2}-1\right\}$, we have $w\left(u_{1}, v_{i+1}\right) \geq w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ since $w_{1}\left(u_{1}, v_{i+1}\right)=w_{1}\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}$ and $w_{2}\left(u_{1}, v_{i+1}\right) \geq w_{2}\left(u_{1}, v_{i}\right)$. In addition, $w\left(u_{n_{1}}, v_{i}\right) \leq w\left(u_{1}, v_{i}\right)+\left(\frac{2 n_{1}}{3}+k_{1}-1\right)+k_{2}\left(n_{1}-1\right)$ since $w_{1}\left(u_{n_{1}}, v_{i}\right) \leq w_{1}\left(u_{1}, v_{i}\right)+\left(\frac{2 n_{1}}{3}+k_{1}-1\right)$ and $w_{2}\left(u_{n_{1}}, v_{i}\right)=w_{2}\left(u_{1}, v_{i}\right)+d\left(v_{i}\right)\left(n_{1}-1\right) \leq w_{2}\left(u_{1}, v_{i}\right)+k_{2}\left(n_{1}-1\right)$. Therefore, $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq$ $\left(w\left(u_{1}, v_{i}\right)+\frac{n_{1} k_{1}^{2}}{2}\right)-\left(w\left(u_{1}, v_{i}\right)+\left(\frac{2 n_{1}}{3}+k_{1}-1\right)+k_{2}\left(n_{1}-1\right)\right)=n_{1}\left(\frac{k_{1}^{2}}{2}-\frac{2}{3}-k_{2}\right)+k_{2}-k_{1}+1$.

Since $k_{2}<\frac{k_{1}^{2}}{2}$, there are two cases: $k_{2} \leq \frac{k_{1}^{2}}{2}-2$ or $k_{2}=\frac{k_{1}^{2}}{2}-1$. If $k_{2} \leq \frac{k_{1}^{2}}{2}-2, w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq$ $n_{1}\left(\frac{k_{1}^{2}}{2}-\frac{2}{3}-k_{2}\right)+k_{2}-k_{1}+1>n_{1}+k_{2}-k_{1}>0\left(\right.$ since $\left.n_{1}>k_{1}\right)$. If $k_{2}=\frac{k_{1}^{2}}{2}-1, w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right) \geq$ $n_{1}\left(\frac{k_{1}^{2}}{2}-\frac{2}{3}-k_{2}\right)+k_{2}-k_{1}+1>\frac{k_{1}^{2}}{2}-k_{1}>0\left(\right.$ since $\left.k_{1} \geq 4\right)$. Thus, in either case, we have $w\left(u_{1}, v_{i+1}\right)-w\left(u_{n_{1}}, v_{i}\right)>0$, for $i=1, \ldots, n_{2}-1$.

Therefore, (1) holds, the labeling for $k_{1} \geq 3$ is antimagic.

## 6. Concluding remarks and open problems

Since the Eulerian circuit of an Eulerian graph (consequently the trails in the Listing Theorem) can be efficiently computed, the proofs in this paper provide efficient algorithms for finding the antimagic labelings.

It is easy to see that, for cycles, the 2 -approximate magicness result in Lemma 2.2 is the best possible (i.e., 2 cannot be improved to 0 or 1 ). For $n$-vertex $k$-regular $(k>2)$ connected graphs, it may be interesting to prove that they are $\delta$-approximately magic for some $\delta<\left(\frac{n k}{2}-1\right)$ in case $k$ is odd, or $\delta<k$ in case $k$ is even, or, to prove some lower bounds on $\delta$.
